Abstract

For about 20 years now, the word "Fieldbus" has been very widely used. Its common meaning is a network for connecting field devices such as sensors, actuators, field controllers such as PLCs, regulators, drives, controllers, etc., and Human Machine Interfaces (HMI). One of the most important Fieldbus systems is the actuator-sensor interface (AS-i) which is the standard solution for simple, cost-effective networking of sensors and actuators in the field. AS-Interface has established a strong position throughout the automation technology industry.

The actuator-sensor interface (AS-i) replaces conventional wiring technology on the sensor actuator level. AS-i has firmly established itself as a worldwide standard for the cost-effective transfer of power and signals along a single cable. It is an open system and is compatible with all common Fieldbus systems.

The AS-i has many advantages as it minimizes installation costs with high noise immunity during data transfer. AS-i is flexible as signals and power are transferred along a reverse polarity protected yellow flat cable.

The AS-i gateway controls the AS-i system and transmits process data to all types of higher-level control in a standardized I/O map. The AS-i adopts the role of a conventional I/O card in the controller, which allows a simple changeover.

In this study, we will explain the AS-i Fieldbus, its advantages, network structure, system components and message frame structure. A practical setup illustrates how to implement the AS-i Fieldbus as a solution in the field applications.
